

ÖMER FARUK TONBUL

Game Developer (Unity / C#) — Computer Engineering Graduate
Kocaeli / Gebze, Turkey • omer.faruk.15356789@gmail.com

LinkedIn: linkedin.com/in/omerfttonbul • GitHub: github.com/OmerFaruk15356
Portfolio: omefaruk153.itch.io

SUMMARY

Computer Engineering graduate from İstanbul Ticaret University, working with Unity and C# for the past three years on mobile and PC game projects.

Experience covers multiplayer networking with Photon Fusion 2 and PUN2, core gameplay programming, editor tooling for level designers, and performance work on low-end devices. Looking for a junior game developer role on a team that ships original games.

EDUCATION

B.Sc. in Computer Engineering Graduated June 2026
İstanbul Ticaret University — GPA: 3.37 / 4.00

EXPERIENCE

Game Developer Intern | Undoco Games Apr 2025 – Present
Remote

- Contribute to gameplay programming on unpublished mobile and PC titles as part of a small remote team.
- Work with Unity multiplayer networking (Photon Fusion 2), Unity Gaming Services Cloud Code, and IK and ragdoll setup.
- Handle Android publishing tasks, including Firebase integration and Google Play Console setup, and contribute to game and level design decisions.

IT Intern | BDH – Bilişim Destek Hizmetleri Jul 2024 – Aug 2024
Maltepe, İstanbul, Turkey

- Diagnosed and resolved hardware and software problems for internal users.
- Provided first-line technical support for common IT requests.
- Assisted with routine system maintenance and software updates across office workstations.

PROJECTS

Block Knights — Mobile Block Puzzle Game | Undoco Games Feb 2026 – Present
Unity 6 (C#, URP 2D) · iOS & Android · Team of 9

- Team project in the block-puzzle genre, combining grid-based block placement and line clearing with a kingdom-building meta layer.
- Built the core gameplay systems: scoring and combo logic, win and lose checks, drag-and-drop placement, deck refill, grid-line detection, and the ability system (line blast, board shuffle, deck refresh).
- Developed the visual effects and game-feel layer — placement animations, tiered line-clear effects, combo feedback, and camera shake — all driven by a single tunable configuration asset.
- Designed the adaptive difficulty system, driven by one parameter over piece generation with a rescue rule for near-full boards, and defined the obstacle and boss-level mechanics used across the game.
- Built the server-side economy and progression services on Unity Cloud Code, integrated Google Play Games sign-in, and improved performance on low-end Android devices through texture compression and sprite atlasing.

Cherry Island — Online Multiplayer Race Game | Undoco Games Apr 2025 – Jan 2026
Unity 2022.3 (C#), Photon Fusion · PC & Mobile · Team of 7

- Elimination-style party race game in which players run through obstacle-filled levels to reach the finish line first.
- Built the lobby and matchmaking flow — session list, create and join, ready-up, countdown, and handoff into the race scene — including the logic that closes a session to new players once the match starts.
- Wrote the server-side race manager (ready checks, countdown, first-place detection, round resets) and the respawn system, which falls back from the last checkpoint to the parkour start and then to a fixed spawn point.
- Designed the level mechanics — catapults, pendulums, moving and rotating platforms, slides, trampolines, push zones, checkpoints, and coin pickups — with server-authoritative knockback over RPC so that every client sees the same result.
- Set up player movement and the camera on Photon Fusion's kinematic character controller, tuning separate gravity and acceleration values for jump feel, and added mobile support (floating analog stick, touch UI) through the same input path as the keyboard controls.

Unity 6 (C#) · iOS & Android · Team of 11

- Prototype built for an external client, in which players explore the seabed, open chests, and answer questions that test what they have learned.
- Built the submarine player controller — acceleration and deceleration, turn-based tilt, boost zones, and knockback on collisions — tuned to be forgiving for young players, with soft collision that slows the submarine near the map borders instead of stopping it.
- Designed the oxygen system, which works as both fuel and timer (bubble refills, boost drain, mistake penalties) and ties the pace of exploration to the star rating of each level.
- Set up the event-driven architecture the game runs on — an event bus connecting interaction, oxygen, quiz, tutorial, puzzle, and game state, plus singleton managers for shared services — so that UI and gameplay scripts stay decoupled, and built the tutorial system with per-level step data.
- Built the collectible and interaction system (treasures, chests, oxygen bubbles, sea garbage, bottled notes, golden rings) behind a shared interface, applying OOP and SOLID principles so that new interactable types can be added without changing existing code, together with the quiz layer that gives the game its educational core.

Eva — 3D Atmospheric Puzzle-Platformer | Undoco Games

Jun 2025 – Nov 2025

Unity 2022.3 (C#, URP) · PC · Team of 9

- Built the player character controller from scratch as a state machine (walk, run, crouch, turn, jump, climb, hide), with the animator driven by the same state so that movement and animation never disagree.
- Tuned jump feel in detail: coyote time, input buffering before landing, variable jump height, separate rise and fall gravity, and dual-point ground checks to avoid falling off edges by mistake.
- Wrote the path system the game runs on, in which levels are laid out as bezier splines and the character follows the closest point on the curve, giving a side-on feel inside a full 3D scene.
- Built the matching Unity editor tool, which lets level designers drag control points, add or remove curve segments, and smooth paths directly in the scene view without touching code.
- Built the checkpoint system, which saves and restores moved objects and enemies so that a reload brings the level back exactly as it was.
- Built the interaction and puzzle mechanics — levers, gas valves, pushable crates, two-handed pickups, doors, elevators, moving wagons, and ledge climbing — along with patrol and path-following behavior for the two main enemy types.

Shelf Anomaly Detection — Hybrid Computer Vision System | İstanbul Ticaret University

Jan 2026 – Jun 2026

Computer Engineering Capstone · Team of 3

- Built a real-time retail shelf auditing system that detects and classifies three types of anomaly — missing, fallen, and misplaced products — from a single shelf photo.
- Fine-tuned YOLOv8 on the SKU110K dataset and combined it with DBSCAN shelf-row clustering and ResNet-18 embedding similarity, using Laplacian edge-density validation and adaptive IQR fencing to filter out false positives.
- Delivered the full stack: a FastAPI inference service exposing REST endpoints (image upload returning JSON results and an annotated image) and a native Android client built in Kotlin and Jetpack Compose with CameraX, Retrofit, and an MVVM architecture.

The-Door — 2D Pixel-Art Escape Room | Solo Game Jam Project

Feb 10–17, 2024

Unity (C#) · Playable build: omefaruk153.itch.io/the-door

- 2D pixel-art escape room built for a game jam on the theme "What is Behind the Door?".
- Players move between rooms, gather information from objects, solve puzzles, and use what they find to unlock new areas and reach the front door of the house.

Multiplayer Space War — Real-Time Online 2D Arena Shooter | Personal Project*Unity 2021.3 LTS (C#), Photon PUN2 · Play in browser: omefaruk153.itch.io/online-spacewar*

- Real-time online multiplayer 2D space shooter built from scratch, using Photon PUN2 for networked movement, combat, and state sync — RPCs, PhotonView ownership, networked instantiation, and Master Client authority with host migration.
- Designed a data-driven ship and enemy system with ScriptableObjects (three ship classes, three meteor variants), so that balance can be changed without touching code.
- Built the core gameplay loop: XP and leveling with spendable stat points, an ammo-and-reload combat system, a shrinking battle-royale safe zone, and collision damage with kill attribution.
- Implemented a live scoreboard synchronized across clients through Photon custom properties, handling mid-match joins, disconnects, and re-sorting in real time.
- Managed development with a feature-branch and pull-request Git workflow across a three-scene architecture (Loading → Lobby → Game).

SKILLS**Game Development:** Unity (3 yrs), C# (3 yrs), Photon Fusion 2, Photon PUN2, Unity Gaming Services (UGS)

Mobile & Backend: Firebase, Google Play Console, Kotlin / Jetpack Compose, FastAPI

Data / CV: Python, YOLOv8

Other: Java, C, MySQL, Git

CERTIFICATIONS
